## Data Sheet

## FEATURES

JESD204B Subclass 0 or Subclass 1 coded serial digital outputs Signal-to-noise ratio (SNR) = $\mathbf{7 0 . 6} \mathbf{~ d B F S}$ at $\mathbf{1 8 5} \mathbf{~ M H z ~ A I N ~ a n d ~}$ 250 MSPS
Spurious-free dynamic range (SFDR) $\mathbf{= 8 8} \mathbf{~ d B c}$ at $185 \mathbf{~ M H z}$ AIN and 250 MSPS
Total power consumption: $\mathbf{7 1 1} \mathbf{~ m W}$ at $\mathbf{2 5 0}$ MSPS
1.8 V supply voltages

Integer 1-to-8 input clock divider
Sample rates of up to $\mathbf{2 5 0}$ MSPS
IF sampling frequencies of up to $\mathbf{4 0 0} \mathbf{~ M H z}$
Internal analog-to-digital converter (ADC) voltage reference
Flexible analog input range
1.4 V p-p to 2.0 V p-p (1.75 V p-p nominal)

ADC clock duty cycle stabilizer (DCS)
95 dB channel isolation/crosstalk
Serial port control
Energy saving power-down modes
User-configurable, built-in self-test (BIST) capability

## APPLICATIONS

## Diversity radio systems

Multimode digital receivers (3G)
TD-SCDMA, WiMAX, WCDMA, CDMA2000, GSM, EDGE, LTE
DOCSIS 3.0 CMTS upstream receive paths
HFC digital reverse path receivers
I/Q demodulation systems
Smart antenna systems
Electronic test and measurement equipment Radar receivers
COMSEC radio architectures
IED detection/jamming systems
General-purpose software radios
Broadband data applications

## PRODUCT HIGHLIGHTS

1. Integrated dual, 14 -bit, $170 \mathrm{MSPS} / 250 \mathrm{MSPS}$ ADC.
2. The configurable JESD204B output block supports up to 5 Gbps per lane.
3. An on-chip, phase-locked loop (PLL) allows users to provide a single ADC sampling clock; the PLL multiplies the ADC sampling clock to produce the corresponding JESD204B data rate clock.
4. Support for an optional RF clock input to ease system board design.
5. Proprietary differential input maintains excellent SNR performance for input frequencies of up to 400 MHz .
6. Operation from a single 1.8 V power supply.
7. Standard serial port interface (SPI) that supports various product features and functions such as controlling the clock DCS, power-down, test modes, voltage reference mode, over range fast detection, and serial output configuration.

## REVISION HISTORY

## 10/12-Revision 0: Initial Version

## GENERAL DESCRIPTION

The AD9250 is a dual, 14-bit ADC with sampling speeds of up to 250 MSPS. The AD9250 is designed to support communications applications where low cost, small size, wide bandwidth, and versatility are desired.
The ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. The ADC cores feature wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations. A duty cycle stabilizer is provided to compensate for variations in the ADC clock duty cycle, allowing the converters to maintain excellent performance. The JESD204B high speed serial interface reduces board routing requirements and lowers pin count requirements for the receiving device.

By default, the ADC output data is routed directly to the two JESD204B serial output lanes. These outputs are at CML voltage levels. Four modes support any combination of $\mathrm{M}=1$ or 2 (single or dual converters) and $\mathrm{L}=1$ or 2 (one or two lanes). For dual ADC mode, data can be sent through two lanes at the maximum sampling rate of 250 MSPS. However, if data is sent through one lane, a sampling rate of up to 125 MSPS is supported. Synchronization inputs (SYNCINB $\pm$ and SYSREF $\pm$ ) are provided.
Flexible power-down options allow significant power savings, when desired. Programmable overrange level detection is supported for each channel via the dedicated fast detect pins.

Programming for setup and control are accomplished using a 3-wire SPI-compatible serial interface.
The AD9250 is available in a 48 -lead LFCSP and is specified over the industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. This product is protected by a U.S. patent.

## SPECIFICATIONS <br> ADC DC SPECIFICATIONS

AVDD $=1.8 \mathrm{~V}, \mathrm{DRVDD}=1.8 \mathrm{~V}, \mathrm{DVDD}=1.8 \mathrm{~V}$, maximum sample rate for speed grade, VIN $=-1.0 \mathrm{dBFS}$ differential input, 1.75 V p-p full-scale input range, duty cycle stabilizer (DCS) enabled, link parameters used were $\mathrm{M}=2$ and $\mathrm{L}=2$, unless otherwise noted.

|  |  | Min | Typ | Max | Min | Typ | Max |  |
| TWO-TONE SFDR |  |  |  |  |  |  |  |  |
| $\mathrm{f}_{\text {IN }}=184.12 \mathrm{MHz}(-7 \mathrm{dBFS}), 187.12 \mathrm{MHz}(-7 \mathrm{dBFS})$ | $25^{\circ} \mathrm{C}$ |  | 87 |  |  | 84 |  | dBc |
| CROSSTALK ${ }^{2}$ | Full |  | 95 |  |  | 95 |  | dB |
| FULL POWER BANDWIDTH ${ }^{3}$ | $25^{\circ} \mathrm{C}$ |  | 1000 |  |  | 1000 |  | MHz |

${ }^{1}$ See the AN-835 Application Note, Understanding High Speed ADC Testing and Evaluation, for a complete set of definitions.
${ }^{2}$ Crosstalk is measured at 100 MHz with -1.0 dBFS on one channel and no input on the alternate channel.
${ }^{3}$ Full power bandwidth is the bandwidth of operation determined by where the spectral power of the fundamental frequency is reduced by 3 dB .

## DIGITAL SPECIFICATIONS

$\mathrm{AVDD}=1.8 \mathrm{~V}, \mathrm{DRVDD}=1.8 \mathrm{~V}, \mathrm{DVDD}=1.8 \mathrm{~V}$, maximum sample rate for speed grade, VIN $=-1.0 \mathrm{dBFS}$ differential input, 1.75 V p-p full-scale input range, DCS enabled, link parameters used were $M=2$ and $L=2$, unless otherwise noted.

| ENVIRONMENTAL |  |
| Operating Temperature Range (Ambient) | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature Under Bias | $150^{\circ} \mathrm{C}$ |
| Storage Temperature Range (Ambient) | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL CHARACTERISTICS

The exposed paddle must be soldered to the ground plane for the LFCSP package. This increases the reliability of the solder joints, maximizing the thermal capability of the package.

Table 7. Thermal Resistance

| Package Type | Airflow <br> Velocity <br> $(\mathbf{m} / \mathbf{s e c})$ | $\boldsymbol{\theta}_{\mathrm{JA}}{ }^{\mathbf{1 , 2}}$ | $\boldsymbol{\theta}_{\mathrm{Jc}}{ }^{\mathbf{1 , 3}}$ | $\boldsymbol{\theta}_{\mathrm{JB}}{ }^{\mathbf{1 , 4}}$ | Unit |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 48-Lead LFCSP | 0 | 25 | 2 | 14 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $7 \mathrm{~mm} \times 7 \mathrm{~mm}$ | 1.0 | 22 |  |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| (CP-48-13) | 2.5 | 20 |  |  | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

${ }^{1}$ Per JEDEC 51-7, plus JEDEC 25-5 2S2P test board.
${ }^{2}$ Per JEDEC JESD51-2 (still air) or JEDEC JESD51-6 (moving air).
${ }^{3}$ Per MIL-STD-883, Method 1012.1.
${ }^{4}$ Per JEDEC JESD51-8 (still air).

Typical $\theta_{\text {IA }}$ is specified for a 4-layer printed circuit board (PCB) with a solid ground plane. As shown in Table 7, airflow increases heat dissipation, which reduces $\theta_{\text {IA }}$. In addition, metal in direct contact with the package leads from metal traces, through holes, ground, and power planes reduces the $\theta_{I A}$.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 4. Pin Configuration (Top View)

Table 8. Pin Function Descriptions

| Pin No. | Mnemonic | Type | Description |
| :---: | :---: | :---: | :---: |
| ADC Power Supplies |  |  |  |
| 1, 5, 8, 36, 37, 40, 41, 43, 44, 47, 48 | AVDD | Supply | Analog Power Supply (1.8V Nominal). |
| 9, 11, 13, 16, 24, 25, 30 | DVDD | Supply | Digital Power Supply (1.8V Nominal). |
| 12, 28, 29, 35 | DNC |  | Do Not Connect. |
| 17, 23 | DGND |  | Ground Reference for DVDD. |
| 20 | DRVDD | Supply | JESD204B PHY Serial Output Driver Supply (1.8 V Nominal). Note that the DRVDD power is referenced to the AGND Plane. |
| Exposed Paddle | AGND/DRGND | Ground | The exposed thermal paddle on the bottom of the package provides the ground reference for DRVDD and AVDD. This exposed paddle must be connected to ground for proper operation. |
| ADC Analog |  |  |  |
| 2 | RFCLK | Input | ADC RF Clock Input. |
| 3 | CLK- | Input | ADC Nyquist Clock Input-Complement. |
| 4 | CLK+ | Input | ADC Nyquist Clock Input-True. |
| 38 | VIN-A | Input | Differential Analog Input Pin (-) for Channel A. |
| 39 | VIN+A | Input | Differential Analog Input Pin (+) for Channel A. |
| 42 | VCM | Output | Common-Mode Level Bias Output for Analog Inputs. Decouple this pin to ground using a $0.1 \mu \mathrm{~F}$ capacitor. |
| 45 | VIN+B | Input | Differential Analog Input Pin (+) for Channel B. |
| 46 | VIN-B | Input | Differential Analog Input Pin (-) for Channel B. |
| ADC Fast Detect Outputs |  |  |  |
| 26 | FDB | Output | Channel B Fast Detect Indicator (CMOS Levels). |
| 27 | FDA | Output | Channel A Fast Detect Indicator (CMOS Levels). |
| Digital Inputs |  |  |  |
| 6 | SYSREF+ | Input | Active Low JESD204B LVDS SYSREF Input-True |
| 7 | SYSREF- | Input | Active Low JESD204B LVDS SYSREF Input-Complement. |
| 14 | SYNCINB+ | Input | Active Low JESD204B LVDS SYNC Input-True |
| 15 | SYNCINB- | Input | Active Low JESD204B LVDS SYNC Input-Complement. |

| Pin No. | Mnemonic | Type | Description |
| :--- | :--- | :--- | :--- |
| Data Outputs |  |  |  |
| 18 | SERDOUT1+ | Output | Lane B CML Output Data-True. |
| 19 | SERDOUT1- | Output | Lane B CML Output Data-Complement. |

## THEORY OF OPERATION

The AD9250 has two analog input channels and two JESD204B output lanes. The signal passes through several stages before appearing at the output port(s).
The dual ADC design can be used for diversity reception of signals, where the ADCs operate identically on the same carrier but from two separate antennae. The ADCs can also be operated with independent analog inputs. The user can sample frequencies from dc to 300 MHz using appropriate low-pass or band-pass filtering at the ADC inputs with little loss in ADC performance. Operation to 400 MHz analog input is permitted but occurs at the expense of increased ADC noise and distortion.
A synchronization capability is provided to allow synchronized timing between multiple devices.
Programming and control of the AD9250 are accomplished using a 3-pin, SPI-compatible serial interface.

## ADC ARCHITECTURE

The AD9250 architecture consists of a dual, front-end, sample-and-hold circuit, followed by a pipelined switched capacitor ADC. The quantized outputs from each stage are combined into a final 14-bit result in the digital correction logic. The pipelined architecture permits the first stage to operate on a new input sample and the remaining stages to operate on the preceding samples. Sampling occurs on the rising edge of the clock.
Each stage of the pipeline, excluding the last, consists of a low resolution flash ADC connected to a switched capacitor digital-to-analog converter (DAC) and an interstage residue amplifier (MDAC). The MDAC magnifies the difference between the reconstructed DAC output and the flash input for the next stage in the pipeline. One bit of redundancy is used in each stage to facilitate digital correction of flash errors. The last stage simply consists of a flash ADC.
The input stage of each channel contains a differential sampling circuit that can be ac- or dc-coupled in differential or singleended modes. The output staging block aligns the data, corrects errors, and passes the data to the output buffers. The output buffers are powered from a separate supply, allowing digital output noise to be separated from the analog core.

## ANALOG INPUT CONSIDERATIONS

The analog input to the AD9250 is a differential, switched capacitor circuit that has been designed for optimum performance while processing a differential input signal.
The clock signal alternatively switches the input between sample mode and hold mode (see the configuration shown in Figure 34). When the input is switched into sample mode, the signal source must be capable of charging the sampling capacitors and settling within $1 / 2$ clock cycle.

A small resistor in series with each input can help reduce the peak transient current required from the output stage of the driving source. A shunt capacitor can be placed across the inputs to provide dynamic charging currents. This passive network creates a low-pass filter at the ADC input; therefore, the precise values are dependent on the application.
In intermediate frequency (IF) undersampling applications, reduce the shunt capacitors. In combination with the driving source impedance, the shunt capacitors limit the input bandwidth. Refer to the AN-742 Application Note, Frequency Domain Response of Switched-Capacitor ADCs; the AN-827 Application Note, A Resonant Approach to Interfacing Amplifiers to SwitchedCapacitor ADCs; and the Analog Dialogue article, "TransformerCoupled Front-End for Wideband A/D Converters," for more information on this subject.

Figure 34. Switched-Capacitor Input
For best dynamic performance, match the source impedances driving VIN+ and VIN- and differentially balance the inputs.

## Input Common Mode

The analog inputs of the AD9250 are not internally dc biased. In ac-coupled applications, the user must provide this bias externally. Setting the device so that $\mathrm{V}_{\mathrm{CM}}=0.5 \times \mathrm{AVDD}$ (or 0.9 V ) is recommended for optimum performance. An on-board common-mode voltage reference is included in the design and is available from the VCM pin. Using the VCM output to set the input common mode is recommended. Optimum performance is achieved when the common-mode voltage of the analog input is set by the VCM pin voltage (typically $0.5 \times \mathrm{AVDD}$ ). Decouple the VCM pin to ground by using a $0.1 \mu \mathrm{~F}$ capacitor, as described in the Applications Information section. Place this decoupling capacitor close to the pin to minimize the series resistance and inductance between the part and this capacitor.

## Differential Input Configurations

Optimum performance is achieved while driving the AD9250 in a differential input configuration. For baseband applications, the AD8138, ADA4937-2, ADA4938-2, and ADA4930-2 differential drivers provide excellent performance and a flexible interface to the ADC.

The output common-mode voltage of the ADA4930-2 is easily set with the VCM pin of the AD9250 (see Figure 35), and the driver can be configured in a Sallen-Key filter topology to provide band-limiting of the input signal.

Figure 35. Differential Input Configuration Using the ADA4930-2
For baseband applications where SNR is a key parameter, differential transformer coupling is the recommended input configuration. An example is shown in Figure 36. To bias the analog input, the VCM voltage can be connected to the center tap of the secondary winding of the transformer.

Figure 36. Differential Transformer-Coupled Configuration
Consider the signal characteristics when selecting a transformer. Most RF transformers saturate at frequencies below a few megahertz. Excessive signal power can also cause core saturation, which leads to distortion.

At input frequencies in the second Nyquist zone and above, the noise performance of most amplifiers is not adequate to achieve the true SNR performance of the AD9250. For applications where SNR is a key parameter, differential double balun coupling is the recommended input configuration (see Figure 37). In this configuration, the input is ac-coupled and the VCM voltage is provided to each input through a $33 \Omega$ resistor. These resistors compensate for losses in the input baluns to provide a $50 \Omega$ impedance to the driver.

Figure 37. Differential Double Balun Input Configuration

In the double balun and transformer configurations, the value of the input capacitors and resistors is dependent on the input frequency and source impedance. Based on these parameters, the value of the input resistors and capacitors may need to be adjusted or some components may need to be removed. Table 9 displays recommended values to set the RC network for different input frequency ranges. However, these values are dependent on the input signal and bandwidth and should be used only as a starting guide. Note that the values given in Table 9 are for each R1, R2, C1, C2, and R3 components shown in Figure 36 and Figure 37.

Table 9. Example RC Network

| Frequency <br> Range <br> (MHz) | R1 <br> Series <br> $\mathbf{( \Omega )}$ | C1 <br> Differential <br> (pF) | R2 <br> Series <br> $\mathbf{( \Omega )}$ | C2 <br> Shunt <br> (pF) | R3 <br> Shunt <br> $(\boldsymbol{\Omega})$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 to 100 | 33 | 8.2 | 0 | 15 | 49.9 |
| 100 to 300 | 15 | 3.9 | 0 | 8.2 | 49.9 |

An alternative to using a transformer-coupled input at frequencies in the second Nyquist zone is to use an amplifier with variable gain. The AD8375 or AD8376 digital variable gain amplifier (DVGAs) provides good performance for driving the AD9250. Figure 38 shows an example of the AD8376 driving the AD9250 through a band-pass antialiasing filter.

Figure 38. Differential Input Configuration Using the AD8376

## VOLTAGE REFERENCE

A stable and accurate voltage reference is built into the AD9250. The full-scale input range can be adjusted by varying the reference voltage via the SPI. The input span of the ADC tracks the reference voltage changes linearly.

## CLOCK INPUT CONSIDERATIONS

The AD9250 has two options for deriving the input sampling clock, a differential Nyquist sampling clock input or an RF clock input (which is internally divided by 4). The clock input is selected in Register 0x09 and by default is configured for the Nyquist clock input. For optimum performance, clock the AD9250 Nyquist sample clock input, CLK+ and CLK-, with a differential signal. The signal is typically ac-coupled into the CLK+ and CLK- pins via a transformer or via capacitors. These pins are biased internally (see Figure 39) and require no external bias. If the clock inputs are floated, CLK- is pulled slightly lower than CLK+ to prevent spurious clocking.

## Nyquist Clock Input Options

The AD9250 Nyquist clock input supports a differential clock between 40 MHz to 625 MHz . The clock input structure supports differential input voltages from 0.3 V to 3.6 V and is therefore compatible with various logic family inputs, such as CMOS, LVDS, and LVPECL. A sine wave input is also accepted, but higher slew rates typically provide optimal performance. Clock source jitter is a critical parameter that can affect performance, as described in the Jitter Considerations section. If the inputs are floated, pull the CLK- pin low to prevent spurious clocking.
The Nyquist clock input pins, CLK+ and CLK-, are internally biased to 0.9 V and have a typical input impedance of 4 pF in parallel with $10 \mathrm{k} \Omega$ (see Figure 39). The input clock is typically ac-coupled to CLK+ and CLK-. Some typical clock drive circuits are presented in Figure 40 through Figure 43 for reference.

Figure 39. Equivalent Nyquist Clock Input Circuit
For applications where a single-ended low jitter clock between 40 MHz to 200 MHz is available, an RF transformer is recommended. An example using an RF transformer in the clock network is shown in Figure 40. At frequencies above 200 MHz , an RF balun is recommended, as seen in Figure 41. The back-toback Schottky diodes across the transformer secondary limit clock excursions into the AD9250 to approximately 0.8 V p-p differential. This limit helps prevent the large voltage swings of the clock from feeding through to other portions of the AD9250, yet preserves the fast rise and fall times of the clock, which are critical to low jitter performance.

Figure 40. Transformer-Coupled Differential Clock (Up to 200 MHz)

Figure 41. Balun-Coupled Differential Clock (Up to 625 MHz)
In some cases, it is desirable to buffer or generate multiple clocks from a single source. In those cases, Analog Devices, Inc., offers clock drivers with excellent jitter performance. Figure 42 shows a typical PECL driver circuit that uses PECL drivers such
as the AD9510, AD9511, AD9512, AD9513, AD9514, AD9515, AD9516, AD9517, AD9518, AD9520, AD9522, AD9523, AD9524, and ADCLK905, ADCLK907, and ADCLK925.

Figure 42. Differential PECL Sample Clock (Up to 625 MHz)
Analog Devices also offers LVDS clock drivers with excellent jitter performance. A typical circuit is shown in Figure 43 and uses LVDS drivers such as the AD9510, AD9511, AD9512, AD9513, AD9514, AD9515, AD9516, AD9517, AD9518, AD9520, AD9522, AD9523, and AD9524.

Figure 43. Differential LVDS Sample Clock (Up to 625 MHz)

## RF Clock Input Options

The AD9250 RF clock input supports a single-ended clock between 625 GHz to 1.5 GHz . The equivalent RF clock input circuit is shown in Figure 44. The input is self biased to 0.9 V and is typically ac-coupled. The input has a typical input impedance of $10 \mathrm{k} \Omega$ in parallel with 1 pF at the RFCLK pin.

Figure 44. Equivalent RF Clock Input Circuit
It is recommended to drive the RF clock input of the AD9250 with a PECL or sine wave signal with a minimum signal amplitude of 600 mV peak to peak. Regardless of the type of signal being used, clock source jitter is of the most concern, as described in the Jitter Considerations section. Figure 45 shows the preferred method of clocking when using the RF clock input on the AD9250. It is recommended to use a $50 \Omega$ transmission line to route the clock signal to the RF clock input of the AD9250 due to the high frequency nature of the signal and terminate the transmission line close to the RF clock input.

Figure 45. Typical RF Clock Input Circuit

Figure 46. Differential PECL RF Clock Input Circuit

Figure 46 shows the RF clock input of the AD9250 being driven from the LVPECL outputs of the AD9515. The differential LVPECL output signal from the AD9515 is converted to a singleended signal using an RF balun or RF transformer. The RF balun configuration is recommended for clock frequencies associated with the RF clock input.

## Input Clock Divider

The AD9250 contains an input clock divider with the ability to divide the Nyquist input clock by integer values between 1 and 8 . The RF clock input uses an on-chip predivider to divide the clock input by four before it reaches the 1 to 8 divider. This allows higher input frequencies to be achieved on the RF clock input. The divide ratios can be selected using Register 0x09 and Register 0x0B. Register 0x09 is used to set the RF clock input, and Register 0x0B can be used to set the divide ratio of the 1-to-8 divider for both the RF clock input and the Nyquist clock input. For divide ratios other than 1 , the duty-cycle stabilizer is automatically enabled.

Figure 47. AD9250 Clock Divider Circuit
The AD9250 clock divider can be synchronized using the external SYSREF input. Bit 1 and Bit 2 of Register 0x3A allow the clock divider to be resynchronized on every SYSREF signal or only on the first signal after the register is written. A valid SYSREF causes the clock divider to reset to its initial state. This synchronization feature allows multiple parts to have their clock dividers aligned to guarantee simultaneous input sampling.

## Clock Duty Cycle

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals and, as a result, may be sensitive to clock duty cycle. Commonly, a $\pm 5 \%$ tolerance is required on the clock duty cycle to maintain dynamic performance characteristics.
The AD9250 contains a DCS that retimes the nonsampling (falling) edge, providing an internal clock signal with a nominal $50 \%$ duty cycle. This allows the user to provide a wide range of clock input duty cycles without affecting the performance of the AD9250.

Jitter on the rising edge of the input clock is still of paramount concern and is not reduced by the duty cycle stabilizer. The duty cycle control loop does not function for clock rates less than 40 MHz nominally. The loop has a time constant associated with it that must be considered when the clock rate can change dynamically. A wait time of $1.5 \mu \mathrm{~s}$ to $5 \mu \mathrm{~s}$ is required after a dynamic clock frequency increase or decrease before the DCS loop is relocked to the input signal. During the time that the loop is not locked, the DCS loop is bypassed, and the internal device timing is dependent on the duty cycle of the input clock signal. In such applications, it may be appropriate to disable the duty cycle stabilizer. In all other applications, enabling the DCS circuit is recommended to maximize ac performance.

## Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. The degradation in SNR at a given input frequency $\left(\mathrm{f}_{\mathrm{IN}}\right)$ due to jitter $\left(\mathrm{t}_{\mathrm{J}}\right)$ can be calculated by

$$
S N R_{H F}=-10 \log \left[\left(2 \pi \times f_{I N} \times t_{J R M S}\right)^{2}+10^{\left(-S N R_{L F} / 10\right)}\right]
$$

In the equation, the rms aperture jitter represents the root-meansquare of all jitter sources, which include the clock input, the analog input signal, and the ADC aperture jitter specification. IF undersampling applications are particularly sensitive to jitter, as shown in Figure 48.

Figure 48. AD9250-250 SNR vs. Input Frequency and Jitter

Treat the clock input as an analog signal in cases where aperture jitter may affect the dynamic range of the AD9250. Separate the power supplies for the clock drivers from the ADC output driver supplies to avoid modulating the clock signal with digital noise. Low jitter, crystal controlled oscillators make the best clock sources. If the clock is generated from another type of source (by gating, dividing, or another method), retime it by the original clock at the last step.

Refer to the AN-501 Application Note, Aperture Uncertainty and ADC System Performance, and the AN-756 Application Note, Sampled Systems and the Effects of Clock Phase Noise and Jitter, for more information about jitter performance as it relates to ADCs.

## POWER DISSIPATION AND STANDBY MODE

As shown in Figure 49, the power dissipated by the AD9250 is proportional to its sample rate. The data in Figure 49 was taken using the same operating conditions as those used for the Typical Performance Characteristics section.

Figure 49. AD9250-250 Power vs. Encode Rate

By asserting PDWN (either through the SPI port or by asserting the PDWN pin high), the AD9250 is placed in power-down mode. In this state, the ADC typically dissipates about 9 mW . Asserting the PDWN pin low returns the AD9250 to its normal operating mode.

Low power dissipation in power-down mode is achieved by shutting down the reference, reference buffer, biasing networks, and clock. Internal capacitors are discharged when entering powerdown mode and then must be recharged when returning to normal operation. As a result, wake-up time is related to the time spent in power-down mode, and shorter power-down cycles result in proportionally shorter wake-up times.
When using the SPI port interface, the user can place the ADC in power-down mode or standby mode. Standby mode allows the user to keep the internal reference circuitry powered when faster wake-up times are required. See the Memory Map Register Description section and the AN-877 Application Note, Interfacing to High Speed ADCs via SPI, for additional details.

## DIGITAL OUTPUTS

## JESD204B Transmit Top Level Description

The AD9250 digital output uses the JEDEC Standard No. JESD204B, Serial Interface for Data Converters. JESD204B is a protocol to link the AD9250 to a digital processing device over a serial interface of up to 5 Gbps link speeds (3.5 Gbps, 14-bit ADC data rate). The benefits of the JESD204B interface include a reduction in required board area for data interface routing and the enabling of smaller packages for converter and logic devices. The AD9250 supports single or dual lane interfaces.

## JESD204B Overview

The JESD204B data transmit block assembles the parallel data from the ADC into frames and uses $8 \mathrm{~b} / 10 \mathrm{~b}$ encoding as well as optional scrambling to form serial output data. Lane synchronization is supported using special characters during the initial establishment of the link, and additional synchronization is embedded in the data stream thereafter. A matching external receiver is required to lock onto the serial data stream and recover the data and clock. For additional details on the JESD204B interface, refer to the JESD204B standard.

The AD9250 JESD204B transmit block maps the output of the two ADCs over a link. A link can be configured to use either single or dual serial differential outputs that are called lanes. The JESD204B specification refers to a number of parameters to define the link, and these parameters must match between the JESD204B transmitter (AD9250 output) and receiver.

The JESD204B link is described according to the following parameters:

- $\mathrm{S}=$ samples transmitted/single converter/frame cycle ( AD 9250 value $=1$ )
- $\mathrm{M}=$ number of converters/converter device (AD9250 value $=2$ by default, or can be set to 1$)$
- $\mathrm{L}=$ number of lanes/converter device (AD9250 value $=1$ or 2 )
- $\mathrm{N}=$ converter resolution $(\mathrm{AD} 9250$ value $=14)$
- $\mathrm{N}^{\prime}=$ total number of bits per sample (AD9250 value $=16$ )
- $\quad \mathrm{CF}=$ number of control words/frame clock cycle/converter device (AD9250 value $=0$ )
- $\mathrm{CS}=$ number of control bits/conversion sample (configurable on the AD9250 up to 2 bits)
- $\mathrm{K}=$ number of frames per multiframe (configurable on the AD9250)
- $\mathrm{HD}=$ high density mode $(\mathrm{AD} 9250$ value $=0)$
- $\mathrm{F}=$ octets/frame (AD9250 value $=2$ or 4 , dependent upon $\mathrm{L}=2$ or 1 )
- $\mathrm{C}=$ control bit (overrange, overflow, underflow; available on the AD9250)
- $\quad \mathrm{T}=$ tail bit (available on the AD9250)
- SCR = scrambler enable/disable (configurable on the AD9250)
- $\quad \mathrm{FCHK}=$ checksum for the JESD204B parameters (automatically calculated and stored in register map)

Figure 50 shows a simplified block diagram of the AD9250 JESD204B link. By default, the AD9250 is configured to use two converters and two lanes. Converter A data is output to SERDOUT0+/SERDOUT0-, and Converter B is output to SERDOUT1+/SERDOUT1-. The AD9250 allows for other configurations such as combining the outputs of both converters onto a single lane or changing the mapping of the A and B digital output paths. These modes are setup through a quick configuration register in the SPI register map, along with additional customizable options.

By default in the AD9250, the 14-bit converter word from each converter is broken into two octets ( 8 bits of data). Bit 0 (MSB) through Bit 7 are in the first octet. The second octet contains Bit 8 through Bit 13 (LSB) and two tail bits. The tail bits can be configured as zeros, pseudo-random number sequence or control bits indicating overrange, underrange, or valid data conditions.
The two resulting octets can be scrambled. Scrambling is optional; however, it is available to avoid spectral peaks when transmitting similar digital data patterns. The scrambler uses a self synchronizing, polynomial-based algorithm defined by the equation $1+x^{14}+x^{15}$. The descrambler in the receiver should be a self-synchronizing version of the scrambler polynomial.

The two octets are then encoded with an $8 \mathrm{~b} / 10 \mathrm{~b}$ encoder. The 8b/10b encoder works by taking eight bits of data (an octet) and encoding them into a 10 -bit symbol. Figure 51 shows how the 14 -bit data is taken from the ADC, the tail bits are added, the two octets are scrambled, and how the octets are encoded into two 10 -bit symbols. Figure 51 illustrates the default data format.

At the data link layer, in addition to the $8 \mathrm{~b} / 10 \mathrm{~b}$ encoding, the character replacement is used to allow the receiver to monitor frame alignment. The character replacement process occurs on the frame and multiframe boundaries, and implementation depends on which boundary is occurring, and if scrambling is enabled.

If scrambling is disabled, the following applies. If the last scrambled octet of the last frame of the multiframe equals the last octet of the previous frame, the transmitter replaces the last octet with the control character $/ \mathrm{A} /=/ \mathrm{K} 28.3 /$. On other frames within the multiframe, if the last octet in the frame equals the last octet of the previous frame, the transmitter replaces the last octet with the control character /F/=/K28.7/.
If scrambling is enabled, the following applies. If the last octet of the last frame of the multiframe equals $0 \times 7 \mathrm{C}$, the transmitter replaces the last octet with the control character / A/ = /K28.3/. On other frames within the multiframe, if the last octet equals 0 xFC , the transmitter replaces the last octet with the control character /F/ = /K28.7/.

Refer to JEDEC Standard No. 204B-July 2011 for additional information about the JESD204B interface. Section 5.1 covers the transport layer and data format details and Section 5.2 covers scrambling and descrambling.

## JESD204B Synchronization Details

The AD9250 is a JESD204B Subclass 1 device and establishes synchronization of the link through two control signals, SYSREF and SYNC, and typically a common device clock. SYSREF and SYNC are common to all converter devices for alignment purposes at the system level.
The synchronization process is accomplished over three phases: code group synchronization (CGS), initial lane alignment sequence (ILAS), and data transmission. If scrambling is enabled, the bits are not actually scrambled until the data transmission phase, and the CGS phase and ILAS phase do not use scrambling.

## CGS Phase

In the CGS phase, the JESD204B transmit block transmits /K28.5/ characters. The receiver (external logic device) must locate K28.5 characters in its input data stream using clock and data recovery (CDR) techniques.

Once a certain number of consecutive K28.5 characters have been detected on the link lanes, the receiver initiates a SYSREF edge so that the AD9250 transmit data establishes a local multiframe clock (LMFC) internally.
The SYSREF edge also resets any sampling edges within the ADC to align sampling instances to the LMFC. This is important to maintain synchronization across multiple devices.

The receiver or logic device de-asserts the SYNC~ signal (SYNCINB $\pm$ ), and the transmitter block begins the ILAS phase.

## ILAS Phase

In the ILAS phase, the transmitter sends out a known pattern, and the receiver aligns all lanes of the link and verifies the parameters of the link.
The ILAS phase begins after SYNC~ has been de-asserted (goes high). The transmit block begins to transmit four multiframes. Dummy samples are inserted between the required characters so that full multiframes are transmitted. The four multiframes include the following:

- Multiframe 1: Begins with an /R/ character [K28.0] and ends with an /A/ character [K28.3].
- Multiframe 2: Begins with an /R/ character followed by a /Q/ [K28.4] character, followed by link configuration parameters over 14 configuration octets (see Table 10), and ends with an /A/ character.
- Multiframe 3: Is the same as Multiframe 1.
- Multiframe 4: Is the same as Multiframe 1.

## Data Transmission Phase

In the data transmission phase, frame alignment is monitored with control characters. Character replacement is used at the end of frames. Character replacement in the transmitter occurs in the following instances:

- If scrambling is disabled and the last octet of the frame or multiframe equals the octet value of the previous frame.
- If scrambling is enabled and the last octet of the multiframe is equal to 0 x 7 C , or the last octet of a frame is equal to 0 xFC .

Table 10. Fourteen Configuration Octets of the ILAS Phase

| No. | Bit 7 <br> (MSB) | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | $\begin{aligned} & \text { Bit } 0 \\ & \text { (LSB) } \end{aligned}$ |

## Link Setup Parameters

The following demonstrates how to configure the AD9250 JESD204B interface. The steps to configure the output include the following:

1. Disable lanes before changing configuration
2. Select quick configuration option
3. Configure detailed options
4. Check FCHK, checksum of JESD204B interface parameters
5. Set additional digital output configuration options
6. Re-enable lane(s)

## Disable Lanes Before Changing Configuration

Before modifying the JESD204B link parameters, disable the link and hold it in reset. This is accomplished by writing Logic 1 to Register 0x5F, Bit[0].

## Select Quick Configuration Option

Write to Register 0x5E, the 204B quick configuration register to select the configuration options. See Table 13 for configuration options and resulting JESD204B parameter values.

- $0 \times 11=$ one converter, one lane
- $0 \times 12=$ one converter, two lanes
- $0 \times 21=$ two converters, one lane
- $0 \times 22=$ two converters, two lanes

## Configure Detailed Options

Configure the tail bits and control bits.

- With $\mathrm{N}^{\prime}=16$ and $\mathrm{N}=14$, there are two bits available per sample for transmitting additional information over the JESD204B link. The options are tail bits or control bits. By default, tail bits of 0b00 value are used.
- Tail bits are dummy bits sent over the link to complete the two octets and do not convey any information about the input signal. Tail bits can be fixed zeros (default) or psuedo random numbers (Register 0x5F, Bit[6]).
- One or two control bits can be used instead of the tail bits through Register 0x72, Bits[7:6]. The tail bits can be set using Register 0x14, Bits[7:5].

Set lane identification values.

- JESD204B allows parameters to identify the device and lane. These parameters are transmitted during the ILAS phase, and they are accessible in the internal registers.
- There are three identification values: device identification (DID), bank identification (BID), and lane identification (LID). DID and BID are device specific; therefore, they can be used for link identification.

Set number of frames per multiframe, K

- Per the JESD204B specification, a multiframe is defined as a group of $K$ successive frames, where $K$ is between 1 and 32, and it requires that the number of octets be between 17 and 1024. The K value is set to 32 by default in Register 0x70, Bits[7:0]. Note that the K value is the register value plus 1.
- The K value can be changed; however, it must comply with a few conditions. The AD9250 uses a fixed value for octets per frame [F] based on the JESD204B quick configuration setting. K must also be a multiple of 4 and conform to the following equation.

$$
32 \geq K \geq \operatorname{Ceil}(17 / F)
$$

- The JESD204B specification also calls for the number of octets per multiframe ( $\mathrm{K} \times \mathrm{F}$ ) to be between 17 and 1024 . The F value is fixed through the quick configuration setting to ensure this relationship is true.

Table 11. JESD204B Configurable Identification Values

| DID Value | Register, Bits | Value Range |
| :--- | :--- | :--- |
| LID (Lane 0) | $0 \times 67,[4: 0]$ | $0 \ldots 31$ |
| LID (Lane 1) | $0 \times 68,[4: 0]$ | $0 \ldots 31$ |
| DID | $0 \times 64,[7: 0]$ | $0 \ldots 255$ |
| BID | $0 \times 65,[3: 0]$ | $0 \ldots 15$ |

Scramble, SCR.

- Scrambling can be enabled or disabled by setting Register 0x6E, Bit[7]. By default, scrambling is enabled. Per the JESD204B protocol, scrambling is only functional after the lane synchronization has completed.

Select lane synchronization options.
Most of the synchronization features of the JESD204B interface are enabled by default for typical applications. In some cases, these features can be disabled or modified as follows:

- ILAS enabling is controlled in Register 0x5F, Bits[3:2] and by default is enabled. Optionally, to support some unique instances of the interfaces (such as NMCDA-SL), the JESD204B interface can be programmed to either disable the ILAS sequence or continually repeat the ILAS sequence.

The AD9250 has fixed values of some of the JESD204B interface parameters, and they are as follows:

- $\quad[\mathrm{N}]=14$ : number of bits per converter is 14 , in Register 0x72, Bits[4:0]
- $\quad\left[N^{\prime}\right]=16$ : number of bits per sample is 16 , in Register 0x73, Bits[4:0]
- $[C F]=0$ : number of control words/ frame clock cycle/converter is 0 , in Register 0x75, Bits[4:0]

Verify read only values: lanes per link (L), octets per frame (F), number of converters (M), and samples per converter per frame (S). The AD9250 calculates values for some JESD204B parameters based on other settings, particularly the quick configuration register selection. The read only values here are available in the register map for verification.

- [L] = lanes per link can be 1 or 2, read the values from Register 0x6E, Bit[0]
- $\quad[F]=$ octets per frame can be 1,2 , or 4 , read the value from Register 0x6F, Bits[7:0]
- $\quad[\mathrm{HD}]=$ high density mode can be 0 or 1 , read the value from Register 0x75, Bit[7]
- $\quad[\mathrm{M}]=$ number of converters per link can be 1 or 2 , read the value from Register 0x71, Bits[7:0]
- $\quad[S]=$ samples per converter per frame can be 1 or 2 , read the value from Register 0x74, Bits[4:0]

## Check FCHK, Checksum of JESD204B Interface Parameters

The JESD204B parameters can be verified through the checksum value [FCHK] of the JESD204B interface parameters. Each lane has a FCHK value associated with it. The FCHK value is transmitted during the ILAS second multiframe and can be read from the internal registers.

The checksum value is the modulo 256 sum of the parameters listed in the No. column of Table 12. The checksum is calculated by adding the parameter fields before they are packed into the octets shown in Table 12.

The FCHK for the lane configuration for data coming out of Lane 0 can be read from Register 0x79. Similarly, the FCHK for the lane configuration for data coming out of Lane 1 can be read from Register 0x7A.

Table 12. JESD204B Configuration Table Used in ILAS and CHKSUM Calculation

| No. | Bit 7 <br> (MSB) | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 (LSB) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | DID[7:0] |  |  |  |  |  |  |  |
| 1 |  |  |  |  | BID[3:0] |  |  |  |
| 2 |  |  |  | LID[4:0] |  |  |  |  |
| 3 | SCR |  |  | L[4:0] |  |  |  |  |
| 4 | F[7:0] |  |  |  |  |  |  |  |
| 5 |  |  |  | K[4:0] |  |  |  |  |
| 6 | M[7:0] |  |  |  |  |  |  |  |
| 7 | CS[1:0] |  |  | N[4:0] |  |  |  |  |
| 8 | SUBCLASS[2:0] |  |  | N'[4:0] |  |  |  |  |
| 9 | JESDV[2:0] |  |  | S[4:0] |  |  |  |  |
| 10 |  |  |  | CF[4:0] |  |  |  |  |

## Additional Digital Output Configuration Options

Other data format controls include the following:

- Invert polarity of serial output data: Register 0x60, Bit[1]
- ADC data format (offset binary or twos complement): Register 0x14, Bits[1:0]
- Options for interpreting single on SYSREF $\pm$ and SYNCINB $\pm$ : Register 0x3A
- Option to remap converter and lane assignments, Register 0x82 and Register 0x83. See Figure 50 for simplified block diagram.

## Re-Enable Lanes After Configuration

After modifying the JESD204B link parameters, enable the link so that the synchronization process can begin. This is accomplished by writing Logic 0 to Register 0x5F, Bit[0].

Figure 50. AD9250 Transmit Link Simplified Block Diagram

Table 14. AD9250 JESD204B Frame Alignment Monitoring and Correction Replacement Characters

| Scrambling | Lane Synchronization | Character to be Replaced | Last Octet in <br> Multiframe | Replacement Character |
| :--- | :--- | :--- | :--- | :--- |
| Off | On | Last octet in frame repeated from previous frame | No | K28.7 |
| Off | On | Last octet in frame repeated from previous frame | Yes | K28.3 |
| Off | Off | Last octet in frame repeated from previous frame | Not applicable | K28.7 |
| On | On | Last octet in frame equals D28.7 | No | K28.7 |
| On | On | Last octet in frame equals D28.3 | Yes | K28.3 |
| On | Off | Last octet in frame equals D28.7 | Not applicable | K28.7 |

## Frame and Lane Alignment Monitoring and Correction

Frame alignment monitoring and correction is part of the JESD204B specification. The 14 -bit word requires two octets to transmit all the data. The two octets (MSB and LSB), where $\mathrm{F}=2$, make up a frame. During normal operating conditions, frame alignment is monitored via alignment characters, which are inserted under certain conditions at the end of a frame. Table 14 summarizes the conditions for character insertion along with the expected characters under the various operation modes. If lane synchronization is enabled, the replacement character value depends on whether the octet is at the end of a frame or at the end of a multiframe.

Based on the operating mode, the receiver can ensure that it is still synchronized to the frame boundary by correctly receiving the replacement characters.

## Digital Outputs and Timing

The AD9250 has differential digital outputs that power up by default. The driver current is derived on-chip and sets the output current at each output equal to a nominal 4 mA . Each output presents a $100 \Omega$ dynamic internal termination to reduce unwanted reflections.

Place a $100 \Omega$ differential termination resistor at each receiver input to result in a nominal 300 mV peak-to-peak swing at the receiver (see Figure 53). Alternatively, single-ended $50 \Omega$ termination can be used. When single-ended termination is used, the termination voltage should be DRVDD/2; otherwise, ac coupling capacitors can be used to terminate to any singleended voltage.

Figure 53. AC-Coupled Digital Output Termination Example
The AD9250 digital outputs can interface with custom ASICs and FPGA receivers, providing superior switching performance in noisy environments. Single point-to-point network topologies are recommended with a single differential $100 \Omega$ termination resistor placed as close to the receiver logic as possible. The common mode of the digital output automatically biases itself to half the supply of the receiver (that is, the common-mode voltage is 0.9 V for a receiver supply of 1.8 V ) if dc-coupled connecting is used
(see Figure 54). For receiver logic that is not within the bounds of the DRVDD supply, use an ac-coupled connection. Simply place a $0.1 \mu \mathrm{~F}$ capacitor on each output pin and derive a $100 \Omega$ differential termination close to the receiver side.

Figure 54. DC-Coupled Digital Output Termination Example
If there is no far-end receiver termination, or if there is poor differential trace routing, timing errors may result. To avoid such timing errors, it is recommended that the trace length be less than six inches, and that the differential output traces be close together and at equal lengths.

Figure 55 shows an example of the digital output (default) data eye and time interval error (TIE) jitter histogram and bathtub curve for the AD9250 lane running at 5 Gbps .
Additional SPI options allow the user to further increase the output driver voltage swing of all four outputs to drive longer trace lengths (see Register 0x15 in Table 17). The power dissipation of the DRVDD supply increases when this option is used. See the Memory Map section for more details.

The format of the output data is twos complement by default. To change the output data format to offset binary, see the Memory Map section (Register 0x14 in Table 17).

Figure 56. AD9250 Digital Outputs Data Eye, Histogram and Bathtub, External $100 \Omega$ Terminations at 3.4 Gbps

## ADC OVERRANGE AND GAIN CONTROL

In receiver applications, it is desirable to have a mechanism to reliably determine when the converter is about to be clipped. The standard overflow indicator provides delayed information on the state of the analog input that is of limited value in preventing clipping. Therefore, it is helpful to have a programmable threshold below full scale that allows time to reduce the gain before the clip occurs. In addition, because input signals can have significant slew rates, latency of this function is of concern.
Using the SPI port, the user can provide a threshold above which the FD output is active. Bit 0 of Register $0 \times 45$ enables the fast detect feature. Register 0x47 to Register 0x4A allow the user to set the threshold levels. As long as the signal is below the selected threshold, the FD output remains low. In this mode, the magnitude of the data is considered in the calculation of the condition, but the sign of the data is not considered. The threshold detection responds identically to positive and negative signals outside the desired range (magnitude).

## ADC OVERRANGE (OR)

The ADC overrange indicator is asserted when an overrange is detected on the input of the ADC. The overrange condition is determined at the output of the ADC pipeline and, therefore, is subject to a latency of 36 ADC clock cycles. An overrange at the input is indicated by this bit 36 clock cycles after it occurs.

## GAIN SWITCHING

The AD9250 includes circuitry that is useful in applications either where large dynamic ranges exist, or where gain ranging amplifiers are employed. This circuitry allows digital thresholds to be set such that an upper threshold and a lower threshold can be programmed.
One such use is to detect when an ADC is about to reach full scale with a particular input condition. The result is to provide an indicator that can be used to quickly insert an attenuator that prevents ADC overdrive.

## Fast Threshold Detection (FDA and FDB)

The FD indicator is asserted if the input magnitude exceeds the value programmed in the fast detect upper threshold registers, located in Register 0x47 and Register 0x48. The selected threshold register is compared with the signal magnitude at the output of the ADC. The fast upper threshold detection has a latency of 7 clock cycles. The approximate upper threshold magnitude is defined by

$$
\begin{aligned}
& \text { Upper Threshold Magnitude }(\mathrm{dBFS})=20 \log (\text { Threshold } \\
& \text { Magnitude } \left./ 2^{16}\right)
\end{aligned}
$$

The FD indicators are not cleared until the signal drops below the lower threshold for the programmed dwell time. The lower threshold is programmed in the fast detect lower threshold registers, located at Register $0 \times 49$ and Register 0x4A. The fast
detect lower threshold register is a 16 -bit register that is compared with the signal magnitude at the output of the ADC. This comparison is subject to the ADC pipeline latency but is accurate in terms of converter resolution. The lower threshold magnitude is defined by

> Lower Threshold Magnitude $(\mathrm{dBFS})=20 \log ($ Threshold Magnitude $/ 2^{16}$ )

The dwell time can be programmed from 1 to 65,535 sample clock cycles by placing the desired value in the fast detect dwell time registers, located in Register 0x4B and Register 0x4C.

The operation of the upper threshold and lower threshold registers, along with the dwell time registers, is shown in Figure 57.

## DC CORRECTION

Because the dc offset of the ADC may be significantly larger than the signal being measured, a dc correction circuit is included to null the dc offset before measuring the power. The dc correction circuit can also be switched into the main signal path; however, this may not be appropriate if the ADC is digitizing a time-varying signal with significant dc content, such as GSM.

## DC CORRECTION BANDWIDTH

The dc correction circuit is a high-pass filter with a programmable bandwidth (ranging between 0.29 Hz and 2.387 kHz at 245.76 MSPS). The bandwidth is controlled by writing to the 4 -bit dc correction bandwidth select register, located at Register 0x40, Bits[5:2]. The following equation can be used to compute the bandwidth value for the dc correction circuit:

$$
D C \_C o r r \_B W=2^{-k-14} \times f_{\text {CLK }} /(2 \times \pi)
$$

where:
$k$ is the 4-bit value programmed in Bits[5:2] of Register 0x40 (values between 0 and 13 are valid for $k$ ).
$f_{\text {CLK }}$ is the AD9250 ADC sample rate in hertz.

## DC CORRECTION READBACK

The current dc correction value can be read back in Register 0x41 and Register 0x42 for each channel. The dc correction value is a 16-bit value that can span the entire input range of the ADC.

## DC CORRECTION FREEZE

Setting Bit 6 of Register 0x40 freezes the dc correction at its current state and continues to use the last updated value as the dc correction value. Clearing this bit restarts dc correction and adds the currently calculated value to the data.

## DC CORRECTION (DCC) ENABLE BITS

Setting Bit 1 of Register 0x40 enables dc correction for use in the output data signal path.

## BUILT-IN SELF-TEST (BIST) AND OUTPUT TEST

The AD9250 includes built-in test features designed to enable verification of the integrity of each channel as well as facilitate board level debugging. A BIST feature is included that verifies the integrity of the digital datapath of the AD9250. Various output test options are also provided to place predictable values on the outputs of the AD9250.

## BUILT-IN SELF-TEST

The BIST is a thorough test of the digital portion of the selected AD9250 signal path. When enabled, the test runs from an internal pseudo-random noise (PN) source through the digital datapath starting at the ADC block output. The BIST sequence runs for 512 cycles and stops. The BIST signature value for Channel A and/or Channel B is placed in Register 0x24 and Register 0x25. The outputs are connected during this test; therefore, the PN sequence can be observed as it runs. The PN sequence can be continued from its last value or reset from the beginning, based on the value programmed in Register 0x0E, Bit 2. The BIST signature result varies based on the channel configuration.

## SERIAL PORT INTERFACE (SPI)

The AD9250 SPI allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI gives the user added flexibility and customization, depending on the application. Addresses are accessed via the serial port and can be written to or read from via the port. Memory is organized into bytes that can be further divided into fields. These fields are documented in the Memory Map section. For detailed operational information, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## CONFIGURATION USING THE SPI

Three pins define the SPI of this ADC: the SCLK pin, the SDIO pin, and the $\overline{\mathrm{CS}}$ pin (see Table 15). The SCLK (serial clock) pin is used to synchronize the read and write data presented from/to the ADC. The SDIO (serial data input/output) pin is a dual-purpose pin that allows data to be sent and read from the internal ADC memory map registers. The $\overline{\mathrm{CS}}$ (chip select bar) pin is an active low control that enables or disables the read and write cycles.

Table 15. Serial Port Interface Pins

| Pin | Function |
| :--- | :--- |
| SCLK | Serial Clock. The serial shift clock input, which is used to <br> synchronize serial interface, reads and writes. |
| SDIO | Serial Data Input/Output. A dual-purpose pin that <br> typically serves as an input or an output, depending on <br> the instruction being sent and the relative position in the <br> timing frame. <br> Chip Select Bar. An active low control that gates the read <br> and write cycles. |

The falling edge of $\overline{\mathrm{CS}}$, in conjunction with the rising edge of SCLK, determines the start of the framing. An example of the serial timing and its definitions can be found in Figure 58 and Table 5.

Other modes involving the $\overline{\mathrm{CS}}$ are available. The $\overline{\mathrm{CS}}$ can be held low indefinitely, which permanently enables the device; this is called streaming. The $\overline{\mathrm{CS}}$ can stall high between bytes to allow for additional external timing. When $\overline{\mathrm{CS}}$ is tied high, SPI functions are placed in a high impedance mode. This mode turns on any SPI pin secondary functions.
During an instruction phase, a 16-bit instruction is transmitted. Data follows the instruction phase, and its length is determined by the W0 and the W1 bits.

All data is composed of 8 -bit words. The first bit of each individual byte of serial data indicates whether a read or write command is issued. This allows the SDIO pin to change direction from an input to an output.
In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the SDIO pin to change direction from an input to an output at the appropriate point in the serial frame.

Data can be sent in MSB first mode or in LSB first mode. MSB first is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## HARDWARE INTERFACE

The pins described in Table 15 comprise the physical interface between the user programming device and the serial port of the AD9250. The SCLK pin and the $\overline{\mathrm{CS}}$ pin function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.
The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the AN-812 Application Note, Microcontroller-Based Serial Port Interface (SPI) Boot Circuit.
Do not activate the SPI port during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the $\overline{\mathrm{CS}}$ signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9250 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

## SPI ACCESSIBLE FEATURES

Table 16 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in the AN-877 Application Note, Interfacing to High Speed ADCs via SPI. The AD9250 part-specific features are described in the Memory Map Register Description section.

Table 16. Features Accessible Using the SPI

| Feature Name | Description |
| :--- | :--- |
| Mode | Allows the user to set either power-down mode or standby mode |
| Clock | Allows the user to access the DCS via the SPI |
| Offset | Allows the user to digitally adjust the converter offset |
| Test I/O | Allows the user to set test modes to have known data on output bits |
| Output Mode | Allows the user to set up outputs |
| Output Phase | Allows the user to set the output clock polarity |
| Output Delay | Allows the user to vary the DCO delay |
| VREF | Allows the user to set the reference voltage |

Figure 58. Serial Port Interface Timing Diagram

## MEMORY MAP

## READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is roughly divided into three sections: the chip configuration registers (Address $0 \times 00$ to Address $0 \times 02$ ); the channel index and transfer registers (Address 0x05 and Address 0 xFF ); and the ADC functions registers, including setup, control, and test (Address 0x08 to Address 0xA8).

The memory map register table (see Table 17) documents the default hexadecimal value for each hexadecimal address shown. The column with the heading Bit 7 (MSB) is the start of the default hexadecimal value given. For example, Address 0x14, the output mode register, has a hexadecimal default value of $0 \times 01$. This means that Bit $0=1$, and the remaining bits are 0 s . This setting is the default output format value, which is twos complement. For more information on this function and others, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI. This document details the functions controlled by Register $0 \times 00$ to Register $0 \times 25$. The remaining registers, Register 0x3A and Register 0x59, are documented in the Memory Map Register Description section.

## Open and Reserved Locations

All address and bit locations that are not included in Table 17 are not currently supported for this device. Unused bits of a valid address location should be written with 0 s. Writing to these locations is required only when part of an address location is open (for example, Address 0x18). If the entire address location is open (for example, Address 0x13), do not write to this address location.

## Default Values

After the AD9250 is reset, critical registers are loaded with default values. The default values for the registers are given in the memory map register table, Table 17.

## Logic Levels

An explanation of logic level terminology follows:

- "Bit is set" is synonymous with "bit is set to Logic 1 " or "writing Logic 1 for the bit."
- "Clear a bit" is synonymous with "bit is set to Logic 0 " or "writing Logic 0 for the bit."

## Transfer Register Map

Address 0x09, Address 0x0B, Address 0x14, Address 0x18, and Address $0 \times 3 \mathrm{~A}$ to Address $0 \times 4 \mathrm{C}$ are shadowed. Writes to these addresses do not affect part operation until a transfer command is issued by writing $0 \times 01$ to Address 0 xFF , setting the transfer bit. This allows these registers to be updated internally and simultaneously when the transfer bit is set. The internal update takes place when the transfer bit is set, and then the bit autoclears.

## Channel-Specific Registers

Some channel setup functions, such as the signal monitor thresholds, can be programmed to a different value for each channel. In these cases, channel address locations are internally duplicated for each channel. These registers and bits are designated in Table 17 as local. These local registers and bits can be accessed by setting the appropriate Channel A or Channel B bits in Register 0x05. If both bits are set, the subsequent write affects the registers of both channels. In a read cycle, only Channel A or Channel B should be set to read one of the two registers. If both bits are set during an SPI read cycle, the part returns the value for Channel A. Registers and bits designated as global in Table 17 affect the entire part and the channel features for which independent settings are not allowed between channels. The settings in Register 0x05 do not affect the global registers and bits.

## MEMORY MAP REGISTER TABLE

All address and bit locations that are not included in Table 17 are not currently supported for this device.
Table 17. Memory Map Registers

| Reg Addr (Hex) | Register Name | Bit 7 <br> (MSB) | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 (LSB) | Default | Notes |

## MEMORY MAP REGISTER DESCRIPTION

For more information on functions controlled in Register 0x00 to Register 0x25, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## APPLICATIONS INFORMATION

## DESIGN GUIDELINES

Before starting system level design and layout of the AD9250, it is recommended that the designer become familiar with these guidelines, which discuss the special circuit connections and layout requirements needed for certain pins.

## Power and Ground Recommendations

When connecting power to the AD9250, it is recommended that two separate 1.8 V power supplies be used: the power supply for AVDD can be isolated and for DVDD and DRVDD it can be tied together, in which case an isolation inductor of approximately $1 \mu \mathrm{H}$ is recommended. Alternately, the JESD204B PHY power (DRVDD) and analog (AVDD) supplies can be tied together, and a separate supply can be used for the digital outputs (DVDD).
The designer can employ several different decoupling capacitors to cover both high and low frequencies. Locate these capacitors close to the point of entry at the PC board level and close to the pins of the part with minimal trace length.
When using the AD9250, a single PCB ground plane should be sufficient. With proper decoupling and smart partitioning of the PCB analog, digital, and clock sections, optimum performance is easily achieved.

## Exposed Paddle Thermal Heat Slug Recommendations

It is mandatory that the exposed paddle on the underside of the ADC be connected to analog ground (AGND) to achieve the best electrical and thermal performance. Mate a continuous, exposed (no solder mask) copper plane on the PCB to the AD9250 exposed paddle, Pin 0.

The copper plane should have several vias to achieve the lowest possible resistive thermal path for heat dissipation to flow through the bottom of the PCB. These vias should be filled or plugged with nonconductive epoxy.
To maximize the coverage and adhesion between the ADC and the PCB, overlay a silkscreen to partition the continuous plane on the PCB into several uniform sections. This provides several tie points between the ADC and the PCB during the reflow process. Using one continuous plane with no partitions guarantees only one tie point between the ADC and the PCB. See the evaluation board for a PCB layout example. For detailed information about the packaging and PCB layout of chip scale packages, refer to the AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package (LFCSP).

## VCM

Decouple the VCM pin to ground with a $0.1 \mu \mathrm{~F}$ capacitor, as shown in Figure 36. For optimal channel-to-channel isolation, include a $33 \Omega$ resistor between the AD9250 VCM pin and the Channel A analog input network connection, as well as between the AD9250 VCM pin and the Channel B analog input network connection.

## SPI Port

When the full dynamic performance of the converter is required, do not activate the SPI port during periods. Because the SCLK, $\overline{\mathrm{CS}}$, and SDIO signals are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9250 to keep these signals from transitioning at the converter input pins during critical sampling periods.

## OUTLINE DIMENSIONS

*COMPLIANT TO JEDEC STANDARDS MO-220-WKKD-2
WITH EXCEPTION TO EXPOSED PAD DIMENSION.

Figure 59. 48-Lead Lead Frame Chip Scale Package [LFCSP_WQ]
$7 \mathrm{~mm} \times 7 \mathrm{~mm}$ Body, Very Very Thin Quad (CP-48-13)
Dimensions shown in millimeters

| ORDERING GUIDE | Temperature Range | Package Description | Package Option |

NOTES

## NOTES

[^0]:    ${ }^{1}$ Measured with a low input frequency, full-scale sine wave.
    ${ }^{2}$ Input capacitance refers to the effective capacitance between one differential input pin and its complement.
    ${ }^{3}$ Input resistance refers to the effective resistance between one differential input pin and its complement.
    ${ }^{4}$ Standby power is measured with a dc input and the CLK $\pm$ pin active.

[^1]:    ${ }^{1}$ Pull-up.
    ${ }^{2}$ Pull-down.

[^2]:    ${ }^{1}$ Conversion rate is the clock rate after the divider.
    ${ }^{2}$ Refer to Figure 3 for timing diagram.
    ${ }^{3}$ Wake-up time ADC is defined as the time required for the ADC to return to normal operation from power-down mode.
    ${ }^{4}$ Wake-up time output is defined as the time required for JESD204B output to return to normal operation from power-down mode.
    ${ }^{5}$ Cycles refers to ADC conversion rate cycles.

[^3]:    ${ }^{1} Z=$ RoHS Compliant Part.
